

PROLOG PROGRAM FOR MEDICAL DIAGNOSIS

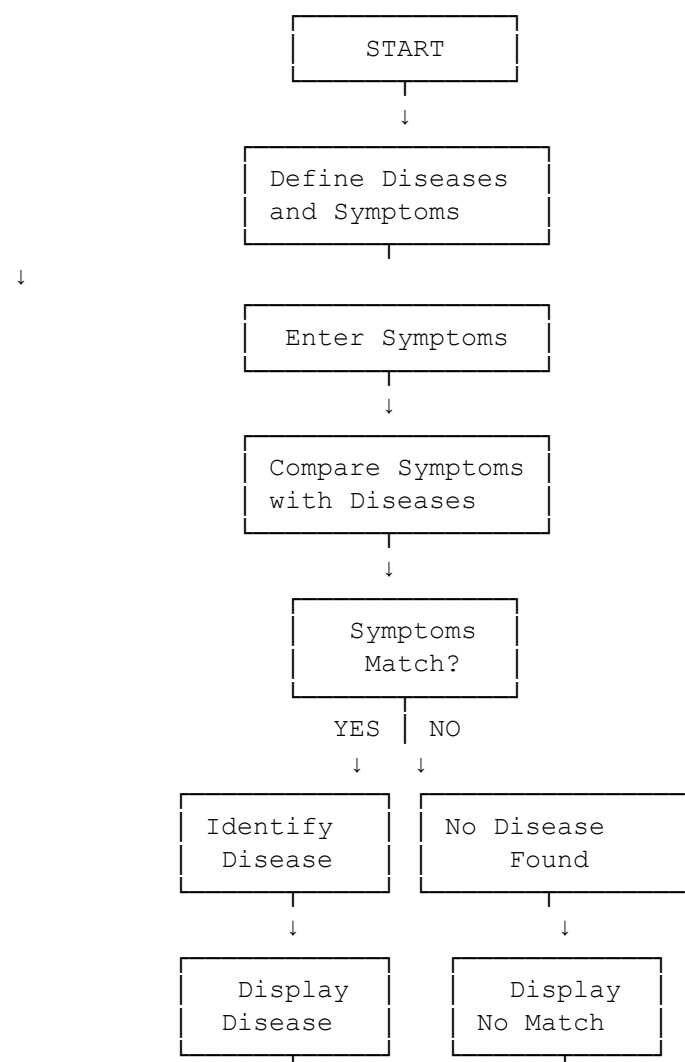

Aim

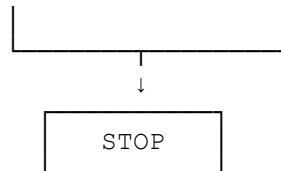

To write a Prolog program to implement a simple **medical diagnosis system** by identifying a possible disease based on the given symptoms.

Algorithm

1. Start.
2. Define diseases and their corresponding symptoms.
3. Accept the symptoms as input.
4. Compare the given symptoms with the predefined disease symptoms.
5. If the symptoms match, identify the corresponding disease.
6. Display the diagnosed disease.
7. If no symptoms match, display **No disease found**.
8. Stop.

Flowchart

Prolog Program

```
% Medical Diagnosis System
```

```
diagnose([fever,cough,cold], flu).  
diagnose([fever,chills,headache], malaria).  
diagnose([fever,headache,stomach_pain], typhoid).  
diagnose([cold,cough,sneezing], common_cold).
```

Query

```
?- diagnose([fever,cough,cold], Disease).
```

OUTPUT

```
?-  
|      disease(flu).  
true.  
  
?- disease(malaria).  
true.  
  
?-
```

Result

```
Disease = flu.
```

Therefore, the medical diagnosis system successfully identifies the disease based on the given symptoms.
